

# Synthesis and Structure of Hexatungstochromate(III), $[H_3Cr^{III}W_6O_{24}]^{6-}$

Wenjing Liu<sup>a</sup>, Zhengguo Lin<sup>a</sup>, Bassem S. Bassil<sup>ab</sup>, Rami Al-Oweini<sup>ac</sup>, and Ulrich Kortz<sup>a\*</sup>

Dedicated to Prof. Hans J. Breunig on the occasion of his 70th birthday

**Abstract:** The hexatungstochromate(III)  $[H_3Cr^{III}W_6O_{24}]^{6-}$  (**1**) was synthesized in aqueous, basic medium by simple reaction of chromium(III) nitrate nonahydrate and sodium tungstate dihydrate in a 1:6 ratio. Polyanion **1** represents the first Anderson-Evans type heteropolytungstate with a trivalent hetero element. The sodium salt of **1** with the formula  $Na_6[H_3Cr^{III}W_6O_{24}] \cdot 22H_2O$  (**1a**) was fully characterized in the solid state by single crystal XRD, FT-IR spectroscopy, and thermogravimetric analysis.

**Keywords:** Anderson-Evans structure · Chromium · Polyoxometalates · XRD

## Introduction

Polyoxometalates (POMs) are discrete, anionic metal-oxygen clusters of early *d* block metal ions in high oxidation states (e.g. W<sup>VI</sup>, Mo<sup>VI</sup>, V<sup>IV</sup>)<sup>[1]</sup> with a very large structural and compositional variety, leading to interest in many different areas including materials science, catalysis, analytical chemistry, magnetism, and biomedical science.<sup>[2]</sup> The number of 3d metal-containing POMs is very large, but only a few structurally characterized chromium-containing POMs are known.<sup>[3]</sup> The main obstacle for the development of Cr-POM chemistry is probably the kinetic inertness of  $[Cr(OH)_6]^{3+}$  towards ligand exchange in aqueous solution.<sup>[4]</sup>

Chromium-containing POMs possess interesting physicochemical properties, and the paramagnetic Cr<sup>III</sup> is EPR active, which can find applications in integrated information storage, quantum computing, molecule-based magnets and spintronics.<sup>[5]</sup> In 1970, Perloff determined the crystal structure of hexamolybdochromate(III)  $[CrMo_6O_{24}H_6]^{3-}$ <sup>[3a]</sup> which was later described by Tsigdinos as  $[CrO_6Mo_6O_{15+n}H_{2n}]^{3-}$ .<sup>[6]</sup> Lunk's<sup>[3c-e]</sup> and

Mialane's<sup>[3j]</sup> groups reported the first structural examples of Cr-containing heteropolytungstates. In 2008, Xue's group reported two Cr<sup>III</sup>-substituted, sandwich-type heteropolytungstates,  $[Cr_2(AsMo_7O_{27})_2]^{12-}$  and  $[CrFe(AsMo_7O_{27})_2]^{12-}$ .<sup>[3h,i]</sup> Recently, our group prepared two mono-Cr<sup>III</sup>-substituted heteropolytungstates  $[Cr^{III}(HX^VW_7O_{28})_2]^{13-}$  (X = P, As) by simple, one pot reactions, and these polyanions exhibit exceptionally large magnetic anisotropy.<sup>[3l]</sup>

An important subclass of POMs is the  $\{XM_6O_{24}\}$  structure type (also known as the Anderson-Evans structure), in which an octahedral  $XO_6$  hetero group is surrounded by six edge-shared  $MO_6$  octahedra. In 1948, Evans<sup>[7]</sup> reported the first example by determining the structure of  $[TeMo_6O_{24}]^{6-}$ , which had originally been proposed by Anderson in 1937.<sup>[8]</sup> To date, a large number of Anderson-Evans type polyanion derivatives  $[H_nXM_6O_{24}]^{m-}$  (M = W, Mo) is known, with many different *p*- and *d*-block elements acting as octahedrally coordinated hetero groups  $XO_6$ , with the oxidation states for X ranging from +2 to +6. The structural characterized tungsten-based derivatives  $[H_nXW_6O_{24}]^{m-}$  include the following hetero elements: Te<sup>VI</sup>,<sup>[9]</sup> Sb<sup>V</sup>,<sup>[10]</sup> V<sup>V</sup>,<sup>[11]</sup> Pt<sup>IV</sup>,<sup>[12]</sup> Mn<sup>IV</sup>,<sup>[13]</sup> Ni<sup>IV</sup>,<sup>[14]</sup> Ni<sup>II</sup>,<sup>[15a,b]</sup> and Mn<sup>II</sup>.<sup>[15c]</sup>

On the other hand, the molybdate family  $[H_nXMo_6O_{24}]^{m-}$  is known for the following hetero elements: I<sup>VII</sup>,<sup>[16]</sup> Te<sup>VI</sup>,<sup>[7,8]</sup> Sb<sup>V</sup>,<sup>[17]</sup> V<sup>V</sup>,<sup>[18]</sup> Pt<sup>IV</sup>,<sup>[19]</sup> Pd<sup>IV</sup>,<sup>[20]</sup> Al<sup>III</sup>,<sup>[21]</sup> Cr<sup>III</sup>,<sup>[3a,g,6,22]</sup> Fe<sup>III</sup>,<sup>[21b]</sup> Co<sup>III</sup>,<sup>[21b,23]</sup> Ga<sup>III</sup>,<sup>[24]</sup> Rh<sup>III</sup>,<sup>[25]</sup> Mn<sup>II</sup>,<sup>[21b]</sup> Co<sup>II</sup>,<sup>[21a,26]</sup> Ni<sup>II</sup>,<sup>[21b,27]</sup> Cu<sup>II</sup>,<sup>[28]</sup> and Zn<sup>II</sup>.<sup>[21b,29]</sup> There are some reports on mixed addenda Anderson-Evans ions, such as  $[Ni^{II}(OH)_6W_xO_{18}]^{4-}$ ,<sup>[30]</sup> which was reinvestigated by Miwa's group.<sup>[21b]</sup>

It has also been demonstrated that organic functionalities can be attached to one or both sides of the Anderson-Evans

framework, in particular by the groups of Hasenkopf,<sup>[31]</sup> Cronin,<sup>[32]</sup> Wang,<sup>[33]</sup> Wei,<sup>[34]</sup> Wu,<sup>[35]</sup> and Song.<sup>[36]</sup>

Here, we report on the synthesis and structure of the chromium-centered Anderson-Evans type polytungstate derivative.

## Experimental Section

### Synthesis

All chemicals were commercially available and used without further purification.

### Synthesis of $Na_6[H_3Cr^{III}W_6O_{24}] \cdot 22H_2O$

#### Method 1

A sample of  $Cr(NO_3)_3 \cdot 9H_2O$  (0.20 g, 0.50 mmol) was dissolved in 20 mL of 1 M sodium acetate solution at pH 6.9, followed by addition of  $Na_2WO_4 \cdot 2H_2O$  (0.99 g, 3.00 mmol). The mixture was stirred for 1 h at 80 °C, allowed to cool to room temperature, and then filtered (final pH 8). Slow evaporation at room temperature led to the formation of green crystals of **1a** within three days (yield 0.15 g, 14%). IR (cm<sup>-1</sup>): 947 (m), 880 (s), 656 (s), 559 (w), 511 (m), 440 (m). Anal. calcd (found): Na 6.71 (7.15), W 53.65 (53.76), Cr 2.53 (2.69). Mw 2076.4 g/mol.

#### Method 2

A sample of  $Cr(NO_3)_3 \cdot 9H_2O$  (0.40 g, 1.00 mmol) was dissolved in 20 mL of 0.5 M sodium acetate solution at pH 6, followed by addition of  $Na_2WO_4 \cdot 2H_2O$  (2.64 g, 8.00 mmol). The mixture was stirred for 1 h at 80 °C, allowed to cool to room temperature, and then filtered (final

pH 8). Slow evaporation at room temperature led to the formation of green crystals of **1a** within two days (yield 0.4 g, 19% based on Cr). The identity of **1a** was established by single crystal XRD and IR.

### Instrumentation

Infrared spectra were recorded on a Nicolet Avatar 370 FT-IR spectrophotometer using KBr pellets. The following abbreviations were used to assign the peak intensities: w = weak; m = medium; s = strong; br = broad. Thermogravimetric analysis was carried out on a TA Instruments SDT Q600 thermobalance with a 100 mL/min flow of nitrogen; the temperature was ramped from 20 to 800 °C at a rate of 5 °C/min. Elemental analysis was performed by CNRS, Service Central d'Analyse, Solaize, France.

### X-ray Crystallography

A single crystal of **1a** was mounted on a Hampton cryoloop in light oil for data collection at 100 K. Data collection and indexing were performed on a Bruker D8 SMART APEX II CCD diffractometer with kappa geometry (graphite monochromator,  $\lambda$  (Mo K $\alpha$ ) = 0.71073 Å). Data integration was performed using SAINT.<sup>[37]</sup> Routine Lorentz and polarization corrections were applied. Multiscan absorption corrections were performed using SADABS.<sup>[38]</sup> Direct methods (*SHELXS*) successfully located the tungsten atoms, and successive Fourier syntheses (*SHELXL*) revealed the remaining atoms.<sup>[38]</sup> Refinements were full-matrix least squares against  $|F|^2$  using all data. In the final refinement, the heavy atoms (Cr, W, Na) of the polyanion were refined anisotropically; the O atoms were refined isotropically. Crystallographic data are summarized in Table 1. The complete X-ray crystallographic data (CIF format) is available free of charge *via* the internet at the Fachinformationszentrum (FIZ) Karlsruhe (<http://www.fiz-karlsruhe.de/icsd.html>) under the CSD number 429800.

## Results and Discussion

### Synthesis and Structure

The novel polyanion  $[\text{H}_3\text{Cr}^{\text{III}}\text{W}_6\text{O}_{24}]^6$  (**1**) was synthesized in a one-pot procedure under conventional ‘open beaker’ conditions, by reaction of  $\text{Cr}(\text{NO}_3)_3 \cdot 9\text{H}_2\text{O}$  with  $\text{Na}_2\text{WO}_4 \cdot 2\text{H}_2\text{O}$  in aqueous  $\text{NaOAc}$  solution at 80 °C. The results show that the optimal ratio of  $\text{Cr}^{3+}/\text{WO}_4^{2-}$  is 1:6 for method 1 and 1:8 for method 2 (see Exp. Section). The ratio of  $\text{Cr}^{3+}/\text{WO}_4^{2-}$  represents the stoichiometric ratio in method 1, but not in 2. The reason is that the final pH is crucial for the successful isolation of **1a**, which should be carefully adjusted to 7.5–8.5. The starting pH in method 1 is 6.9, but 6 in method 2,

Table 1. Crystal data for **1a**.

Compound	$\text{Na}_6[\text{H}_3\text{Cr}^{\text{III}}\text{W}_6\text{O}_{24}] \cdot 22\text{H}_2\text{O}$
Formula weight [g/mol]	2076.4

<sup>a</sup>  $R = \Sigma ||\text{F}_o| - |\text{F}_c|| / \Sigma |\text{F}_o|$ . <sup>b</sup>  $Rw = [\sum w(\text{F}_o^2 - \text{F}_c^2)^2 / \sum w(\text{F}_o^2)^2]^{1/2}$ .

and therefore, an excess of  $\text{Na}_2\text{WO}_4 \cdot 2\text{H}_2\text{O}$  is needed in method 2 to keep the final pH in the range 7.5–8.5.

Single crystal X-ray analysis revealed that  $[\text{H}_3\text{Cr}^{\text{III}}\text{W}_6\text{O}_{24}]^6$  has the so-called Anderson-Evans structure, consisting of a ring of six edge-shared  $\text{WO}_6$  octahedra surrounding the central  $\text{CrO}_6$  unit (Fig. 1). Hence, polyanion **1** represents the first Anderson-Evans type heteropolytungstate with a trivalent hetero element. The title

polyanion is isostructural with the molybdenum derivative  $[\text{Cr}(\text{OH})_6\text{Mo}_6\text{O}_{18}]^{3-}$ , first reported in 1970.<sup>[3a]</sup> The central  $\text{Cr}^{\text{III}}$  ion in **1** has an almost ideal octahedral coordination environment, with Cr–O distances in the range of 1.962(5)–2.006(5) Å. These distances are very similar to those observed in the molybdenum derivative  $[\text{Cr}(\text{OH})_6\text{Mo}_6\text{O}_{18}]^{3-}$  (Cr–O 1.968(3)–1.986(3) Å). The W–O distances in **1** can be grouped in three sets, terminal (W=O<sub>t</sub>,

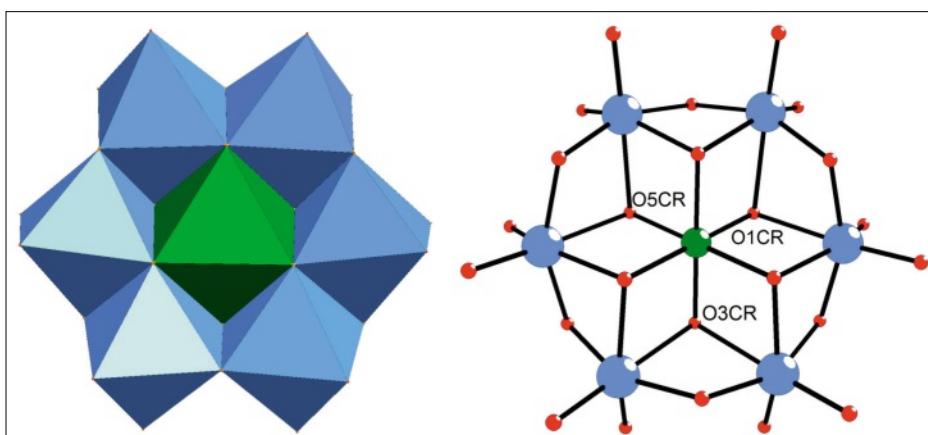

Fig. 1. Polyhedral (left) and ball-and-stick (right) representations of polyanion **1**. The positions of the three oxygens carrying non-disordered protons are indicated. Color code: W atoms and  $\text{WO}_6$  octahedra (blue), Cr atom and  $\text{CrO}_6$  octahedron (green), O atoms (red).

1.722(6)–1.763(6) Å, doubly-bridging ( $\text{W}-\text{O}_b$ : 1.916(6)–1.965(5) Å), and triply-bridging ( $\text{W}-\text{O}_c$ : 2.094(5)–2.413(5) Å). The same trend can be observed for the molybdenum analogue  $[\text{Cr}(\text{OH})_6\text{Mo}_6\text{O}_{18}]^{3-}$  (see Table 2). Bond valence sum (BVS) calculations for **1** suggest that the triply bridging  $\mu_3$ -oxo groups O1CR, O3CR, and O5CR are monoprotonated (1.09, 1.18, and 1.22 respectively). Hence, polyanion **1** is tri-protonated, whereas Perloff's  $[\text{Cr}(\text{OH})_6\text{Mo}_6\text{O}_{18}]^{3-}$  is hexa-protonated, which is probably due to the pH differences during synthesis (8 versus 4.5).

In the solid-state lattice of **1a**, each polyanion is surrounded by five  $\text{Na}^+$  counter cations, which are bound to a total of six terminal  $\text{W}=\text{O}$  oxygens of each polyanion (see Fig. 2). Two nearest neighbor polyanions are linked by the two  $\text{Na}(1)$  ions, and the distance between the central Cr atoms is about 6.771(4) Å. Moreover, the two neighboring polyanions are further linked with other  $\text{Na}^+$  ions to give an extended 3D network.

#### Fourier-transform Infrared Spectrum (FTIR)

The Fourier transform infrared (FTIR) spectrum of **1a** shows a fingerprint region characteristic for the tungsten-oxo framework (Fig. 3). The bands at about 947 cm<sup>-1</sup> and 880 cm<sup>-1</sup> arise from antisymmetric stretching vibrations of the terminal  $\text{W}=\text{O}$  bonds and Cr–O–W bridges, respectively. The strong band at approximately 656 cm<sup>-1</sup> is associated with the antisymmetric stretching of W–O–W bridges, whereas the medium band at 511 cm<sup>-1</sup> and a weak band at 559 cm<sup>-1</sup> correspond to bending vibrations of W–O–W bridges. The medium to strong bands at around 440 cm<sup>-1</sup> originate from the bending vibrations of the Cr–O–W bridges.

#### Thermogravimetric Analysis

The thermogram of **1a** (Fig. 4) shows a weight loss which starts at room temperature with a dehydration step ending at *ca.* 400 °C, corresponding to the loss of ~23 crystal water molecules and further loss of 1.5 compositional waters, involving the protons attached covalently to the polyanion [% calc. (found): 21.7 (20.5)].

#### Conclusions

The Cr<sup>III</sup>-containing hexatungstate  $[\text{H}_3\text{Cr}^{\text{III}}\text{W}_6\text{O}_{24}]^{6-}$  (**1**) was prepared by a simple, one-pot reaction of  $\text{Cr}(\text{NO}_3)_3 \cdot 9\text{H}_2\text{O}$  and  $\text{Na}_2\text{WO}_4 \cdot 2\text{H}_2\text{O}$  in sodium acetate medium. Polyanion **1** represents the first chromium-derivative of the Anderson-Evans type heteropolytungstate family. The title compound was characterized in the solid state by IR spectroscopy, single-crystal

Table 2. Comparison of bond lengths between  $[\text{H}_3\text{Cr}^{\text{III}}\text{W}_6\text{O}_{24}]^{6-}$  (**1**) and  $[\text{Cr}(\text{OH})_6\text{Mo}_6\text{O}_{18}]^{3-}$ .
